WHAT IS GESTATIONAL DIABETES

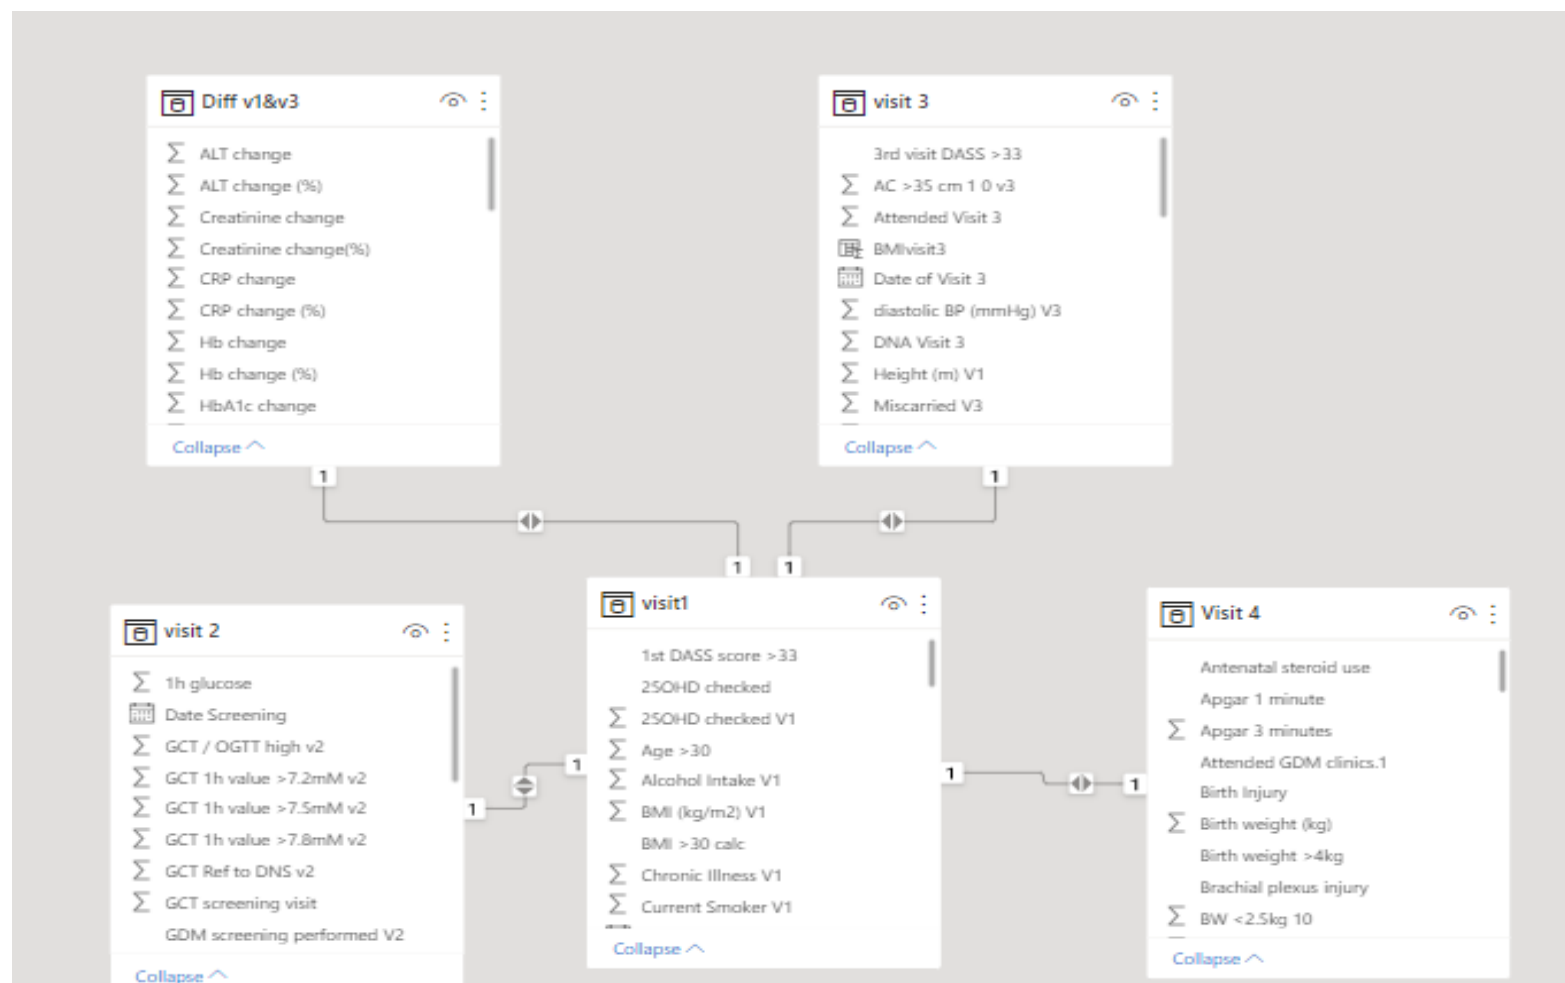

Gestational diabetes is a type of diabetes that can develop during pregnancy in women who don't already have diabetes.

What Causes Gestational Diabetes?

- Gestational diabetes occurs when the body can't make enough insulin during pregnancy. Insulin is a hormone made by the pancreas that acts like a key.
- During pregnancy, the body makes more hormones and goes through other changes, such as weight gain. These changes cause the body's cells to use insulin less effectively, a condition called Insulin resistance increases the body's need for insulin.

- Majority of patients had high Systolic BP
- BMI is greater than 30
- No Birth Injury
- No premature Babies
- Majority of Patients had Vitamin D deficiency even in the Third trimester
- After attending the nutrition and Glucose therapy most of them were able to control their GDM (305 didn't go for therapy)
- High Baby Weight

Patients with GDM & Pre-Diabetes > Age 30

Kidney Analysis

A positive linear correlation was found between urinary albumin and urinary creatinine.

Levels were found to be lower than the normal range in GDM patients and also, a lot of positive and negative variations were seen between the V1 and V3 visits.

Correlation between U Creatinine and U Albumin

U Albumin and U Creatinine Levels in V1 and V3

Maternal and Fetal Complications

Maternal Complications
